RFC 9881

Internet X.509 Public Key Infrastructure -- Algorithm Identifiers for the Module-Lattice-Based Digital Signature Algorithm (ML-DSA)

Abstract

Digital signatures are used within X.509 certificates and Certificate Revocation Lists (CRLs), and to sign messages. This document specifies the conventions for using FIPS 204, the Module-Lattice-Based Digital Signature Algorithm (ML-DSA) in Internet X.509 certificates and CRLs. The conventions for the associated signatures, subject public keys, and private key are also described.

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 7841.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at <https://www.rfc-editor.org/info/rfc9881>.

1. Introduction

The Module-Lattice-Based Digital Signature Algorithm (ML-DSA) is a quantum-resistant digital signature scheme standardized by the US National Institute of Standards and Technology (NIST) PQC project [NIST-PQC] in [FIPS204]. This document specifies the use of the ML-DSA in Public Key Infrastructure X.509 (PKIX) certificates and Certificate Revocation Lists (CRLs) at three security levels: ML-DSA-44, ML-DSA-65, and ML-DSA-87.

[FIPS204] defines two variants of ML-DSA: pure and pre-hash. Only the former is specified in this document. See [Section 8.3](#) for the rationale. The pure variant of ML-DSA supports the typical pre-hash flow. Refer to [Appendix D](#) for more details.

Prior to standardization, ML-DSA was known as Dilithium. ML-DSA and Dilithium are not compatible.

1.1. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

2. Identifiers

The `AlgorithmIdentifier` type is defined in [RFC5912] as follows:

```
AlgorithmIdentifier{ALGORITHM-TYPE, ALGORITHM-TYPE:AlgorithmSet} ::=
  SEQUENCE {
    algorithm    ALGORITHM-TYPE.id({AlgorithmSet}),
    parameters   ALGORITHM-TYPE.
                  Params({AlgorithmSet}{@algorithm}) OPTIONAL
  }
```

NOTE: The above syntax is from [RFC5912] and is compatible with the 2021 ASN.1 syntax [X680]. See [RFC5280] for the 1988 ASN.1 syntax.

The fields in `AlgorithmIdentifier` have the following meanings:

- `algorithm` identifies the cryptographic algorithm with an object identifier (OID).

- parameters, which are optional, are the associated parameters for the algorithm identifier in the algorithm field.

The NIST-registered OIDs [[CSOR](#)] are:

```
id-ml-dsa-44 OBJECT IDENTIFIER ::= { joint-iso-itu-t(2)
    country(16) us(840) organization(1) gov(101) csor(3)
    nistAlgorithm(4) sigAlgs(3) id-ml-dsa-44(17) }

id-ml-dsa-65 OBJECT IDENTIFIER ::= { joint-iso-itu-t(2)
    country(16) us(840) organization(1) gov(101) csor(3)
    nistAlgorithm(4) sigAlgs(3) id-ml-dsa-65(18) }

id-ml-dsa-87 OBJECT IDENTIFIER ::= { joint-iso-itu-t(2)
    country(16) us(840) organization(1) gov(101) csor(3)
    nistAlgorithm(4) sigAlgs(3) id-ml-dsa-87(19) }
```

The contents of the parameters component for each algorithm **MUST** be absent.

3. ML-DSA Signatures in PKIX

ML-DSA is a digital signature scheme built upon the Fiat-Shamir-with-aborts framework [[Fiat-Shamir](#)]. The security is based upon the hardness of lattice problems over module lattices [[Dilithium](#)]. ML-DSA provides three parameter sets for the NIST PQC security categories 2, 3, and 5.

Signatures are used in a number of different ASN.1 structures. As shown in the ASN.1 representation from [[RFC5280](#)] below, in an X.509 certificate, a signature is encoded with an algorithm identifier in the signatureAlgorithm attribute and a signatureValue attribute that contains the actual signature.

```
Certificate ::= SIGNED{ TBSCertificate }

SIGNED{ToBeSigned} ::= SEQUENCE {
    toBeSigned          ToBeSigned,
    algorithmIdentifier SEQUENCE {
        algorithm       SIGNATURE-ALGORITHM,
                       &id({SignatureAlgorithms}),
        parameters      SIGNATURE-ALGORITHM,
                       &Params({SignatureAlgorithms}
                              {@algorithmIdentifier.algorithm})
                       OPTIONAL
    },
    signature BIT STRING (CONTAINING SIGNATURE-ALGORITHM.&Value(
        {SignatureAlgorithms}
        {@algorithmIdentifier.algorithm}))
}
```

Signatures are also used in the CRL list ASN.1 representation from [RFC5280] below. In an X.509 CRL, a signature is encoded with an algorithm identifier in the `signatureAlgorithm` attribute and a `signatureValue` attribute that contains the actual signature.

```
CertificateList ::= SIGNED{ TBSCertList }
```

The following SIGNATURE-ALGORITHM ASN.1 classes are for ML-DSA-44, ML-DSA-65, and ML-DSA-87:

```
sa-ml-dsa-44 SIGNATURE-ALGORITHM ::= {  
  IDENTIFIER id-ml-dsa-44  
  PARAMS ARE absent  
  PUBLIC-KEYS { pk-ml-dsa-44 }  
  SMIME-CAPS { IDENTIFIED BY id-ml-dsa-44 }  
}  
  
sa-ml-dsa-65 SIGNATURE-ALGORITHM ::= {  
  IDENTIFIER id-ml-dsa-65  
  PARAMS ARE absent  
  PUBLIC-KEYS { pk-ml-dsa-65 }  
  SMIME-CAPS { IDENTIFIED BY id-ml-dsa-65 }  
}  
  
sa-ml-dsa-87 SIGNATURE-ALGORITHM ::= {  
  IDENTIFIER id-ml-dsa-87  
  PARAMS ARE absent  
  PUBLIC-KEYS { pk-ml-dsa-87 }  
  SMIME-CAPS { IDENTIFIED BY id-ml-dsa-87 }  
}
```

NOTE: The above syntax is from [RFC5912] and is compatible with the 2021 ASN.1 syntax [X680]. See [RFC5280] for the 1988 ASN.1 syntax.

The identifiers defined in Section 2 can be used as the `AlgorithmIdentifier` in the `signatureAlgorithm` field in the sequence `Certificate/CertificateList` and in the `signature` field in the sequence `TBSCertificate/TBSCertList` in certificates and CRLs, respectively, [RFC5280]. The parameters of these signature algorithms **MUST** be absent, as explained in Section 2. That is, the `AlgorithmIdentifier` **SHALL** be a SEQUENCE of one component, the OID `id-ml-dsa-*`, where `*` is 44, 65, or 87 -- see Section 2.

The `signatureValue` field contains the corresponding ML-DSA signature computed upon the ASN.1 DER-encoded `tbsCertificate/tbsCertList` [RFC5280]. The optional context string (`ctx`) parameter as defined in Section 5.2 of [FIPS204] is left to its default value: the empty string.

Conforming Certification Authority (CA) implementations **MUST** specify the algorithms explicitly by using the OIDs specified in [Section 2](#) when encoding ML-DSA signatures in certificates and CRLs. Conforming client implementations that process certificates and CRLs using ML-DSA **MUST** recognize the corresponding OIDs. Encoding rules for ML-DSA signature values are specified in [Section 2](#).

4. ML-DSA Public Keys in PKIX

In the X.509 certificate, the `subjectPublicKeyInfo` field has the `SubjectPublicKeyInfo` type, which has the following ASN.1 syntax:

```
SubjectPublicKeyInfo {PUBLIC-KEY: IOSet} ::= SEQUENCE {  
    algorithm      AlgorithmIdentifier {PUBLIC-KEY, {IOSet}},  
    subjectPublicKey BIT STRING  
}
```

NOTE: The above syntax is from [\[RFC5912\]](#) and is compatible with the 2021 ASN.1 syntax [\[X680\]](#). See [\[RFC5280\]](#) for the 1988 ASN.1 syntax.

The fields in `SubjectPublicKeyInfo` have the following meaning:

- `algorithm` is the algorithm identifier and parameters for the public key (see above).
- `subjectPublicKey` contains the public key.

Algorithm 22 in Section 7.2 of [\[FIPS204\]](#) defines the raw byte string encoding of an ML-DSA public key. When used in a `SubjectPublicKeyInfo` type, the `subjectPublicKey BIT STRING` contains this raw byte string encoding of the public key. When an ML-DSA public key appears outside of a `SubjectPublicKeyInfo` type in an environment that uses ASN.1 encoding, it could be encoded as an `OCTET STRING` by using the `ML-DSA-44-PublicKey`, `ML-DSA-65-PublicKey`, and `ML-DSA-87-PublicKey` types corresponding to the correct key size defined below.

The PUBLIC-KEY ASN.1 types for ML-DSA are defined here:

```
pk-ml-dsa-44 PUBLIC-KEY ::= {  
  IDENTIFIER id-ml-dsa-44  
  -- KEY no ASN.1 wrapping --  
  CERT-KEY-USAGE  
    { digitalSignature, nonRepudiation, keyCertSign, cRLSign }  
  PRIVATE-KEY ML-DSA-44-PrivateKey } -- defined in Section 6  
  
pk-ml-dsa-65 PUBLIC-KEY ::= {  
  IDENTIFIER id-ml-dsa-65  
  -- KEY no ASN.1 wrapping --  
  CERT-KEY-USAGE  
    { digitalSignature, nonRepudiation, keyCertSign, cRLSign }  
  PRIVATE-KEY ML-DSA-65-PrivateKey } -- defined in Section 6  
  
pk-ml-dsa-87 PUBLIC-KEY ::= {  
  IDENTIFIER id-ml-dsa-87  
  -- KEY no ASN.1 wrapping --  
  CERT-KEY-USAGE  
    { digitalSignature, nonRepudiation, keyCertSign, cRLSign }  
  PRIVATE-KEY ML-DSA-87-PrivateKey } -- defined in Section 6  
  
ML-DSA-44-PublicKey ::= OCTET STRING (SIZE (1312))  
  
ML-DSA-65-PublicKey ::= OCTET STRING (SIZE (1952))  
  
ML-DSA-87-PublicKey ::= OCTET STRING (SIZE (2592))
```

NOTE: The above syntax is from [\[RFC5912\]](#) and is compatible with the 2021 ASN.1 syntax [\[X680\]](#). See [\[RFC5280\]](#) for the 1988 ASN.1 syntax.

[\[RFC5958\]](#) specifies the Asymmetric Key Package's `OneAsymmetricKey` type for encoding asymmetric keypairs. When an ML-DSA private key or keypair is encoded as a `OneAsymmetricKey`, it follows the description in [Section 6](#).

When the ML-DSA private key appears outside of an Asymmetric Key Package in an environment that uses ASN.1 encoding, it can be encoded using one of the `ML-DSA-PrivateKey CHOICE` formats defined in [Section 6](#). The seed format is **RECOMMENDED** as it efficiently stores both the private and public key.

[Appendix C](#) contains example ML-DSA public keys encoded using the textual encoding defined in [\[RFC7468\]](#).

5. Key Usage Bits

The intended application for the key is indicated in the `keyUsage` certificate extension; see [Section 4.2.1.3](#) of [\[RFC5280\]](#). If the `keyUsage` extension is present in a certificate that includes `id-ml-dsa-*` (where `*` is 44, 65, or 87 -- see [Section 2](#)) in the `SubjectPublicKeyInfo`, then the subject public key can only be used for verifying digital signatures on certificates or CRLs, or those used in an entity authentication service, a data origin authentication service, an integrity

service, and/or a non-repudiation service that protects against the signing entity falsely denying some action. This means that the `keyUsage` extension **MUST** have at least one of the following bits set:

- `digitalSignature`
- `nonRepudiation`
- `keyCertSign`
- `cRLSign`

ML-DSA subject public keys cannot be used to establish keys or encrypt data, so the `keyUsage` extension **MUST NOT** have any of the following bits set:

- `keyEncipherment`
- `dataEncipherment`
- `keyAgreement`
- `encipherOnly`
- `decipherOnly`

Requirements about the `keyUsage` extension bits defined in [\[RFC5280\]](#) still apply.

6. Private Key Format

[\[FIPS204\]](#) specifies two formats for an ML-DSA private key: a 32-octet seed (`xi`) and an (expanded) private key. The expanded private key (and public key) is computed from the seed using `ML-DSA.KeyGen_internal(xi)` (algorithm 6).

"Asymmetric Key Packages" [\[RFC5958\]](#) specifies how to encode a private key in a structure that both identifies what algorithm the private key is for and allows for the public key and additional attributes about the key to be included as well. For illustration, the ASN.1 structure `OneAsymmetricKey` is replicated below.

```
OneAsymmetricKey ::= SEQUENCE {  
    version                Version,  
    privateKeyAlgorithm    SEQUENCE {  
        algorithm          PUBLIC-KEY.&id({PublicKeySet}),  
        parameters         PUBLIC-KEY.&Params({PublicKeySet}  
                                {@privateKeyAlgorithm.algorithm})  
                                OPTIONAL}  
    privateKey             OCTET STRING (CONTAINING  
                                PUBLIC-KEY.&PrivateKey({PublicKeySet}  
                                {@privateKeyAlgorithm.algorithm})),  
    attributes             [0] Attributes OPTIONAL,  
    ...  
    [[2: publicKey        [1] BIT STRING (CONTAINING  
                                PUBLIC-KEY.&Params({PublicKeySet}  
                                {@privateKeyAlgorithm.algorithm})  
                                OPTIONAL ]],  
    ...  
}
```

NOTE: The above syntax is from [\[RFC5958\]](#) and is compatible with the 2021 ASN.1 syntax [\[X680\]](#).

For ML-DSA private keys, the `privateKey` field in `OneAsymmetricKey` contains one of the following DER-encoded CHOICE structures. The seed format is a fixed 32-byte OCTET STRING (34 bytes total with the 0x8020 tag and length) for all security levels, while the expandedKey and both formats vary in size by security level:

```
ML-DSA-44-PrivateKey ::= CHOICE {  
  seed [0] OCTET STRING (SIZE (32)),  
  expandedKey OCTET STRING (SIZE (2560)),  
  both SEQUENCE {  
    seed OCTET STRING (SIZE (32)),  
    expandedKey OCTET STRING (SIZE (2560))  
  }  
}  
  
ML-DSA-65-PrivateKey ::= CHOICE {  
  seed [0] OCTET STRING (SIZE (32)),  
  expandedKey OCTET STRING (SIZE (4032)),  
  both SEQUENCE {  
    seed OCTET STRING (SIZE (32)),  
    expandedKey OCTET STRING (SIZE (4032))  
  }  
}  
  
ML-DSA-87-PrivateKey ::= CHOICE {  
  seed [0] OCTET STRING (SIZE (32)),  
  expandedKey OCTET STRING (SIZE (4896)),  
  both SEQUENCE {  
    seed OCTET STRING (SIZE (32)),  
    expandedKey OCTET STRING (SIZE (4896))  
  }  
}
```

NOTE: The above syntax is from [\[RFC5912\]](#) and is compatible with the 2021 ASN.1 syntax [\[X680\]](#). See [\[RFC5280\]](#) for the 1988 ASN.1 syntax.

The CHOICE allows three representations of the private key:

1. The seed format (tag [0]) contains just the 32-byte seed value (xi) from which both the expanded private key and public key can be derived using `ML-DSA.KeyGen_internal(xi)`.
2. The expandedKey format contains the expanded private key that was derived from the seed.
3. The both format contains both the seed and expanded private key, allowing for interoperability; some may want to use and retain the seed and others may only support expanded private keys.

When encoding an ML-DSA private key in a `OneAsymmetricKey` object, any of these three formats may be used, though the seed format is **RECOMMENDED** for storage efficiency.

The `privateKeyAlgorithm` field uses the `AlgorithmIdentifier` structure with the appropriate OID as defined in [Section 2](#). If present, the `publicKey` field will hold the encoded public key as defined in [Section 4](#).

NOTE: While the private key can be stored in multiple formats, the seed-only format is **RECOMMENDED** as it is the most compact representation. Both the expanded private key and the public key can be deterministically derived from the seed using `ML-DSA.KeyGen_internal(xi)`. Alternatively, the public key can be generated from

the private key. While the `publicKey` field and `expandedKey` format are technically redundant when using the seed-only format, they **MAY** be included to enable keypair consistency checks during import operations.

When parsing the private key, the ASN.1 tag explicitly indicates which variant of CHOICE is present. Implementations should use the context-specific tag IMPLICIT [0] (raw value 0x80) for seed, OCTET STRING (0x04) for `expandedKey`, and SEQUENCE (0x30) for both to parse the private key, rather than any other heuristic like length of the enclosing OCTET STRING.

[Appendix C](#) contains example ML-DSA private keys encoded using the textual encoding defined in [\[RFC7468\]](#).

7. IANA Considerations

For the ASN.1 module in [Appendix A](#), IANA has assigned the following object identifier (OID) in the "SMI Security for PKIX Module Identifier" registry (1.3.6.1.5.5.7.0):

Decimal	Description	Reference
119	id-mod-x509-ml-dsa-2025	RFC 9881

Table 1

8. Operational Considerations

8.1. Private Key Format

An `ML-DSA.KeyGen seed (xi)` represents the **RECOMMENDED** format for storing and transmitting ML-DSA private keys. This format is explicitly permitted by [\[FIPS204\]](#) as an acceptable representation of a keypair. In particular, generating the seed in one cryptographic module and then importing or exporting it into another cryptographic module is allowed. The internal key generation function `ML-DSA.KeyGen_internal(xi)` can be accessed for this purpose.

Note also that unlike other private key compression methods in other algorithms, expanding a private key from a seed is a one-way function, meaning that once a full key is expanded from seed and the seed discarded, the seed cannot be recreated, even if the full expanded private key is available. For this reason, it is **RECOMMENDED** that implementations retain and export the seed, even when also exporting the expanded private key. ML-DSA seed extraction can be implemented by including the seed `xi` that is randomly generated at line 1 of Algorithm 1 `ML-DSA.KeyGen` in the returned output.

When encoding an ML-DSA private key in a `OneAsymmetricKey` object, any of these three formats may be used, though the seed format is **RECOMMENDED** for storage efficiency.

8.2. Private Key Consistency Testing

When receiving a private key that contains both the seed and the expandedKey, the recipient **SHOULD** perform a seed consistency check to ensure that the sender properly generated the private key. Recipients that do not perform this seed consistency check avoid keygen and compare operations, but are unable to ensure that the seed and expandedKey match.

If the check is done and the seed and the expandedKey are not consistent, the recipient **MUST** reject the private key as malformed.

The seed consistency check consists of regenerating the expanded form from the seed via `ML-DSA.KeyGen_internal`, and ensuring it is bitwise equal to the value presented in the private key.

[Appendix C.4](#) includes some examples of inconsistent seeds and expanded private keys.

8.3. Rationale for Disallowing HashML-DSA

The HashML-DSA mode defined in Section 5.4 of [\[FIPS204\]](#) **MUST NOT** be used; in other words, public keys identified by `id-hash-ml-dsa-44-with-sha512`, `id-hash-ml-dsa-65-with-sha512`, and `id-hash-ml-dsa-87-with-sha512` **MUST NOT** be in X.509 certificates used for CRLs, OCSP, certificate issuance, and related PKIX protocols. This restriction is primarily to increase interoperability.

ML-DSA and HashML-DSA are incompatible algorithms that require different `Verify()` routines. This introduces the complexity of informing the verifier whether to use `ML-DSA.Verify()` or `HashML-DSA.Verify()`. Additionally, since the same OIDs are used to identify the ML-DSA public keys and ML-DSA signature algorithms, an implementation would need to commit a given public key to be either of type ML-DSA or HashML-DSA at the time of certificate creation. This is anticipated to cause operational issues in contexts where the operator does not know whether the key will need to produce pure or pre-hashed signatures at key-generation time. The External "μ" (GREEK SMALL LETTER MU, U+03BC) mode described in [Appendix D](#) avoids all of these operational concerns.

A minor security reason for disallowing HashML-DSA is that the design of the ML-DSA algorithm provides enhanced resistance against collision attacks, compared with HashML-DSA or conventional RSA or ECDSA signature algorithms. Specifically, ML-DSA prepends the SHAKE256 hash of the public key (`tr`) to the message to-be-signed prior to hashing, as described in line 6 of Algorithm 7 of [\[FIPS204\]](#). This means that in the unlikely discovery of a collision attack against the SHA-3 family, an attacker would have to perform a public-key-specific collision search in order to find message pairs such that $H(tr || m1) = H(tr || m2)$, because a direct hash collision $H(m1) = H(m2)$ will not suffice. HashML-DSA removes this enhanced security property. In spite of its lack of targeted collision protection, the practical security risk of using HashML-DSA in X.509 signatures would be immaterial. This is because a hash of the issuing CA's public

key is already included in the Authority Key Identifier (AKI) extension, which is signed as part of the `tbsCertificate` structure. Even when it is a SHA-1 hash, general second pre-images against the AKI hash of existing issuing CAs would be impractical.

9. Security Considerations

The Security Considerations section of [\[RFC5280\]](#) applies to this specification as well.

The ML-DSA signature scheme is strongly unforgeable under chosen message attacks (SUF-CMA). For the purpose of estimating security strength, it has been assumed that the attacker has access to signatures for no more than 2^{64} chosen messages.

ML-DSA depends on high quality random numbers that are suitable for use in cryptography. The use of inadequate pseudo-random number generators (PRNGs) to generate such values can significantly undermine various security properties. For instance, using an inadequate PRNG for key generation, might allow an attacker to efficiently recover the private key by trying a small set of possibilities, rather than brute-force search the whole keyspace. The generation of random numbers of a sufficient level of quality for use in cryptography is difficult; see Section 3.6.1 of [\[FIPS204\]](#) for some additional information.

In the design of ML-DSA, care has been taken to make side-channel resilience easier to achieve. For instance, ML-DSA does not depend on Gaussian sampling. Implementations must still take great care not to leak information via various side channels. While deliberate design decisions such as these can help to deliver a greater ease of secure implementation -- particularly against side-channel attacks -- it does not necessarily provide resistance to more powerful attacks such as differential power analysis. Some amount of side-channel leakage has been demonstrated in parts of the signing algorithm (specifically the bit-unpacking function), from which a demonstration of key recovery has been made over a large sample of signatures. Masking countermeasures exist for ML-DSA, but comes with performance overhead.

ML-DSA offers both deterministic and randomized signing. Signatures generated with either mode are compatible and a verifier can't tell them apart. In the deterministic case, a signature only depends on the private key and the message to be signed. This makes the implementation easier to test and does not require a randomness source during signing. In the randomized case, signing mixes in a 256-bit random string from an approved random bit generator (RBG). When randomized, ML-DSA is easier to harden against fault and hardware side-channel attacks.

A security property that is also associated with digital signatures is non-repudiation. Non-repudiation refers to the assurance that the owner of a signature key pair that was capable of generating an existing signature corresponding to certain data cannot convincingly deny having signed the data, unless its private key was compromised. The digital signature scheme ML-DSA possesses three security properties beyond unforgeability, that are associated with non-repudiation. These are exclusive ownership, message-bound signatures, and non-resignability. These properties are based tightly on the assumed collision resistance of the hash function used (in this case SHAKE-256). A full discussion of these properties in ML-DSA can be found at [\[CDFJ21\]](#).

Appendix A. ASN.1 Module

This appendix includes the ASN.1 module [X680] for the ML-DSA. Note that as per [RFC5280], certificates use the Distinguished Encoding Rules; see [X690]. This module imports objects from [RFC5912].

Appendix B. Security Strengths

Instead of defining the strength of a quantum algorithm in a traditional manner using the imprecise notion of bits of security, NIST has instead elected to define security levels by picking a reference scheme, which NIST expects to offer notable levels of resistance to both quantum and classical attacks. To wit, an algorithm that achieves NIST PQC security level 1 must require computational resources to break the relevant security property, which are greater than those required for a brute-force key search on AES-128. Levels 3 and 5 use AES-192 and AES-256 as references, respectively. Levels 2 and 4 use collision search for SHA-256 and SHA-384 as references.

The parameter sets defined for NIST security levels 2, 3, and 5 are listed in Figure 1, along with the resulting signature size, public key, and private key sizes in bytes. Note that these are the sizes of the raw keys, not including ASN.1 encoding overhead from `OneAsymmetricKey` and `SubjectPublicKeyInfo` wrappers. Private key sizes are shown for both the seed format and expanded format.

Level	(k,l)	eta	Sig. (B)	Public Key(B)	Private Seed(B)	Private Expand(B)
2	(4,4)	2	2420	1312	32	2560
3	(6,5)	4	3309	1952	32	4032
5	(8,7)	2	4627	2592	32	4896

Table 2: ML-DSA Parameters

Appendix C. Examples

This appendix contains examples of ML-DSA private keys, public keys, certificates, and inconsistent seed and expanded private keys.

C.1. Example Private Keys

The following examples show ML-DSA private keys in different formats, all derived from the same seed `000102...1e1f`. For each security level, we show the seed-only format (using a context-specific `[0]` primitive tag with an implicit encoding of `OCTET STRING`), the expanded format, and both formats together.

NOTE: All examples use the same seed value, showing how the same seed produces different expanded private keys for each security level.

C.1.1. ML-DSA-44 Private Key Examples

Each of the examples includes the textual encoding [RFC7468] followed by the so-called "pretty print"; the private keys are the same.

C.1.1.1. Seed Format

C.1.3. ML-DSA-87 Private Key Examples

Each of the examples includes the textual encoding [RFC7468] followed by the so-called "pretty print"; the private keys are the same.

C.1.3.1. Seed Format

```

-----BEGIN PRIVATE KEY-----
MDQCAQAwCwYJYIZIAWUDBAMTBCKAIAABAgMEBQYHCAkKCwwNDg8QERITFBUWFxgZ
Ghschr4f
-----END PRIVATE KEY-----

```

```

SEQUENCE {
  INTEGER { 0 }
  SEQUENCE {
    OBJECT_IDENTIFIER { 2.16.840.1.101.3.4.3.19 }
  }
  OCTET_STRING {

C.2. Example Public Keys

The following is the ML-DSA-44 public key corresponding to the private key in the previous section. The textual encoding [RFC7468] is followed by the so-called "pretty print"; the public keys are the same.

C.3. Example Certificates

The example certificates in this section have key usage bits set to `digitalSignature`, `keyCertSign`, and `cRLSign` to lessen the number of examples, i.e., brevity. Certificate Policies (CPs) [RFC3647] for production CAs should consider whether this combination is appropriate.

The following is a self-signed certificate for the ML-DSA-44 public key in the previous section. The textual encoding [RFC7468] is followed by the so-called "pretty print"; the certificates are the same.

C.4. Example Inconsistent Seed and Expanded Private Keys

WARNING: These private keys are purposely bad; do not use them in production systems.

The following examples demonstrate inconsistent seed and expanded private keys.

Three `ML-DSA-44-PrivateKey` examples of inconsistent seed and expanded private keys follow:

1. The first `ML-DSA-PrivateKey` example includes the both `CHOICE`, i.e., both `seed` and `expandedKey` are included. The seed and expanded values can be checked for inconsistencies.
2. The second `ML-DSA-PrivateKey` example includes only `expandedKey`. The public key fails to match the `tr` hash value in the private key.
3. The third `ML-DSA-PrivateKey` example also includes only `expandedKey`. The private `s_1` and `s_2` vectors imply a `t` vector whose private low bits do not match the `t_0` vector portion of the private key (its high bits `t_1` are the primary content of the public key).

The second and third examples would not be detected by implementations that do not regenerate the public key from the private key, or neglect to then check consistency of `tr` or `t_0`.

The following is the first example:

-----BEGIN PRIVATE KEY-----

Appendix D. Pre-Hashing (External μ -ML-DSA)

Some applications require pre-hashing that ease operational requirements around large or inconsistently-sized payloads. When signing with pre-hashing, the signature generation process can be separated into a pre-hash step requiring only the message and other public information, and a core signature step that uses the public key.

In the context of ML-DSA, pre-hashing can be performed with the HashML-DSA algorithm defined in Section 5.4 of [FIPS204]. ML-DSA itself supports an External μ pre-hashing mode, which externalizes the message pre-hashing originally performed inside the signing operation. This mode is also laid out in [FIPS204-ExternalMuFAQ]. This document specifies only the use of ML-DSA's External μ mode, and not HashML-DSA, in PKIX for reasons laid out in Section 8.3.

Implementations of ML-DSA using the External μ pre-hashing mode requires the following algorithms, which are modified versions of the algorithms presented in [FIPS204]. The nomenclature used here has been modified from the NIST FAQ [FIPS204-ExternalMuFAQ] for clarity.

Pre-hash operation:

```
Compute $\mu$ (pk, M, ctx):  
  
  # Referred to as 'External $\mu$ -ML-DSA.Prehash(pk, M, ctx)'  
  # in the FIPS 204 FAQ.  
  # M is the message, a bit-string  
  #  $\mu$  and ctx are byte-strings.  
  # ctx is the context string, which defaults to the empty string.  
  
   $\mu$  = H(BytesToBits(H(pk, 64) || IntegerToBytes(0, 1) ||  
                  IntegerToBytes(|ctx|, 1) || ctx) || M, 64)  
  # The functions `BytesToBits` and `IntegerToBytes` are defined  
  # in FIPS 204.  
  return  $\mu$ 
```

Figure 1: Compute μ Prehash Operation

Sign operations:

```

Sign $\mu$ (sk,  $\mu$ ):
    # Referred to as 'External $\mu$ -ML-DSA.Sign(sk,  $\mu$ )'
    # in the FIPS 204 FAQ.

    if | $\mu$ | != 64 then
        return error # return an error indication if the input  $\mu$  is not
                     # 64 bytes.
    end if

    rnd = rand(32) # for the optional deterministic variant,
                  # set rnd to all zeroes
    if rnd = NULL then
        return error # return an error indication if random bit
                     # generation failed
    end if

    sigma = Sign $\mu$ _internal(sk,  $\mu$ , rnd, isExternal $\mu$ =true)
    return sigma

ML-DSA.Sign $\mu$ _internal(sk, M', rnd, isExternal $\mu$ =false):
    #  $\mu$  can be passed as an argument instead of M'
    # defaulting is External $\mu$  to false means that
    # this modified version of Sign_internal can be used
    # in place of the original without interfering with
    # the functioning of pure ML-DSA mode.
    # ... identical to FIPS 204 Algorithm 7, but with Line 6 replaced
    # with
    6: if (isExternal $\mu$ ):
         $\mu$  = M'
    else:
         $\mu$  = H(BytesToBits(tr) || M', 64)

```

Figure 2: The Operations for Signing μ

There is no need to specify an External μ Verify() routine because this is identical to the original ML-DSA.Verify(). This makes External μ mode simply an internal optimization of the signer, and allows an ML-DSA key to sometimes be used with the "one-shot" Sign() API and to sometimes be used with the External μ API without any interoperability concerns.

The External μ mode requires the Compute μ routine to have access to the hash of the signer's public key, which may not be available in some architectures, or require fetching it. That may allow for mismatches between tr and sk. At worst, this will produce a signature that will fail to verify under the intended public key since a compliant Verify() routine will independently compute tr from the public key. This is not believed to be a security concern since μ is never used as-is within ML-DSA.Sign_internal() (Algorithm 7 in [FIPS204]). Rather, it is hashed with values unknown to an attacker on lines 7 and 15. Thus, a signing oracle exposing Sign μ () does not leak any bits of the secret key. The External μ mode also requires SHAKE256 to be available to the Compute μ routine.

Acknowledgments

The authors wish to thank the following people for their contributions to this document: Corey Bonnell, Dierdre Connolly, Viktor Dukhovni, Russ Housley, Alicja Kario, Mike Ounsworth, and Daniel Van Geest.

In addition, we would like to thank those who contributed to the private key format discussion: Tony Arcieri, Bob Beck, Dmitry Belyavskiy, David Benjamin, Daniel Bernstein, Uri Blumenthal, Theo Buehler, Stephen Farrell, Jean-Pierre Fiset, Scott Fluhrer, Alex Gaynor, John Gray, Peter Gutmann, David Hook, Tim Hudson, Paul Kehrer, John Kemp, Watson Ladd, Adam Langley, John Mattsson, Damien Miller, Robert Relyea, Michael Richardson, Markku-Juhani O. Saarinen, Rich Salz, Roland Shoemaker, Sophie Schmieg, Simo Sorce, Michael St. Johns, Falko Strenzke, Filippo Valsorda, Loganaden Velvindron, Carl Wallace, and Wei-Jun Wang.
